## 1 Divide and Conquer

### 1.1 Master Theorem

If  $T(n) = aT(\frac{n}{b}) + O(n^d)$ , where a: num of subproblems; b: subproblem size  $n/b$ ; d: combining time complexity.

$O(n^d)$ : combining time complexity

$$T(n) = \begin{cases} O(n^d) & \text{if } a < b^d \\ O(n^{\log_b a}) & \text{if } a > b^d \\ O(n^d \log n) & \text{if } a = b^d \end{cases} \quad (1)$$

### 1.2 Karatsuba algorithm

For bottom layer,  $3^{\log_2 n} = n^{\log_2 3} = n^{1.6}$  subproblems with linear operation time.  $T(n) = 3T(\frac{n}{2}) + O(n)$ .

---

**Algorithm 1:** Karatsuba algorithm

---

```
1 Input: Two n-digit numbers  $x, y$ .
2 Output: their product
3  $x_L, x_R = \text{leftmost } \lceil n/2 \rceil, \text{rightmost } \lfloor n/2 \rfloor \text{ bits of } x$ 
4  $y_L, y_R = \text{leftmost } \lceil n/2 \rceil, \text{rightmost } \lfloor n/2 \rfloor \text{ bits of } y$ 
5  $P1 = \text{multiply}(x_L, y_L)$ 
6  $P2 = \text{multiply}(x_R, y_R)$ 
7  $P3 = \text{multiply}(x_L + x_R, y_L + y_R)$ 
8 return  $P1 \times 2^n + (P3 - P1 - P2) \times 2^{\frac{n}{2}} + P2$ 
```

---

### 1.3 Inversions

### 1.4 Selection

For **selection**, worst  $O(n)$ , best  $O(\log n)$ . For **quick sort**, if pivot chosen by median of medians,  $O(n \log n)$ , worst  $O(n^2)$ .

### 1.5 median of medians

$$T(n) = T(n/5) + T(7n/10) + O(n)$$

Assume that  $T(n) \leq cn$ ,  $T(\frac{n}{5}) < \frac{cn}{5}$ ,  $T(\frac{7n}{10}) < \frac{7cn}{10}$ ,  $T(n) = T(\frac{n}{5}) + T(\frac{7n}{10}) + O(n) < 0.9cn + bn \leq cn$ . which holds when we set c to be bigger than b.

---

**Algorithm 2:** countInversions

---

**Input:**  $S=(x_1, x_2, \dots, x_n)$ ,  $A:x_1, x_2, \dots, x_{n/2}$ ;  $B:x_{n/2+1}, x_{n/2+2}, \dots, x_n$   
**Output:** Number of Inversions: count

```

1 count=0
2 if  $n == 1$  then
3   | return 0
4 end
5 count+=countInversions(A)+countInversions(B)
6 Maintain 2 pointers  $i = 1, j = n/2 + 1$ ;  $C=\{\}$ 
7 while  $i < n/2$  and  $j < n$  do
8   | if  $x_i < x_j$  then
9     | C.append( $x_{i++}$ )
10  | end
11  | else
12    | C.append( $x_{j++}$ )
13    | count+ =  $j - n/2$ 
14  | end
15 end
16 count+=( $n/2-i$ ) $\times$ ( $j-n/2$ ) # B reached end, while remaining numbers in A are bigger than all B
17 S=C
18 return count
```

---

---

**Algorithm 3:** Select

---

```

1 Choose an arbitrary value  $v$  among  $x_1, x_2, \dots$ ,
2 Divide  $x_1, x_2, \dots, x_n$  into three subsets  $L, M, R$ 
3 if  $k \leq |L|$  then
4   | return Select( $L, k$ )
5 end
6 else if  $|L| < k \leq |L| + |M|$  then
7   | return  $v$ 
8 end
9 else if  $|L| + |M| < k$  then
10  | return Select( $R, k - |L| - |M|$ )
11 end
```

---

## 1.6 Closest Pair

If we sort by y-coordinate every merge step,  $O(n \log n^2)$ , can be improved to  $O(n \log n)$  by plugging it into merge operation.

---

**Algorithm 4:** FindClosestPair
 

---

**Input:** A list of pairs  $P$ :  $p_1 = (a_1, b_1), \dots, p_i = (a_i, b_i), \dots, p_n = (a_n, b_n)$   
**Output:** distance of closest two pairs in  $P$ :  $dist$

- 1 Sort  $P$  by x-coordinate. #  $O(n \log n)$
- 2 Divide  $P$  into two equally sized subsets  $A, B$ , the point in the middle  $p_{mid} = (a_{mid}, b_{mid})$ .
- 3  $dist = \min(\text{FindClosestPair}(A), \text{FindClosestPair}(B))$
- 4 Merge  $A$  and  $B$  by y-coordinate to form  $C$ .
- 5 **foreach**  $c_i = (a_i, b_i)$  **in**  $C$  **do**
- 6     **if**  $|a_i - a_{mid}| < dist$  **then**
- 7         add  $c_i$  to  $S$
- 8     **end**
- 9 **end**
- 10 **foreach**  $s_i = (a_i, b_i)$  **in**  $S$  **do**
- 11      $j = i + 1$
- 12     **while**  $|b_i - b_j| < dist$  **do**
- 13          $dist = \min(dist, \|b_i - b_{i+1}\|)$
- 14          $j = j + 1$
- 15     **end**
- 16 **end**
- 17 **return**  $dist$

---

## 2 Graph

### 2.1 DFS

1. **Tree Edges** Edges in the DFS search:  $(u, v)$  where  $\text{marked}(v) = \text{false}$
2. **Forward Edges** Edges that point to non-child descendants
3. **Back Edges** Edges that point to ancestors
4. **Cross Edges** All the other edges: edges point to vertices on other tree doesn't exist for undirected graph, since if  $(c, f)$  occurs it will only be tree edge.

pre/post ordering for $(u, v)$				Edge type
$\begin{bmatrix} u \\ v \end{bmatrix}$	$\begin{bmatrix} v \\ u \end{bmatrix}$	$\begin{bmatrix} v \\ u \end{bmatrix}$	$\begin{bmatrix} u \\ v \end{bmatrix}$	Tree/forward
$\begin{bmatrix} v \\ v \end{bmatrix}$	$\begin{bmatrix} u \\ u \end{bmatrix}$	$\begin{bmatrix} u \\ u \end{bmatrix}$	$\begin{bmatrix} v \\ v \end{bmatrix}$	Back
$\begin{bmatrix} v \\ v \end{bmatrix}$	$\begin{bmatrix} v \\ v \end{bmatrix}$	$\begin{bmatrix} u \\ u \end{bmatrix}$	$\begin{bmatrix} u \\ u \end{bmatrix}$	Cross

Figure 1: Directed Graph

Figure 2: colored edges

**Algorithm 5:** DFS on Directed Graph

---

```

1  clk=0
2  foreach  $v \in V$  do
3      if  $marked[v]=False$  then
4          explore( $v$ )
5          clk++ # used to calculate the number of connected components
6      end
7  end
8  Function explore( $u$ ):
9      pre[u]=clk
10     clk++
11     visited[u]=false
12     foreach  $(u, v) \in E$  do
13         if  $marked[v]=false$  then
14             explore( $v$ )
15         end
16     end
17     post[u]=clk
18     clk++

```

---

**2.2 strongly connected components**

- Note that we can't simply employ DFS to find C.C., as although you find reachable points from a certain vertex  $v$ , the vertex you explore may not be reachable from each other.
- Note that unlike topological ordering, the node with the earliest post time doesn't necessarily occur in sink SCC, as the vertex with outer edges are revisited where our algorithm ends in somewhere else. i.e., for graph ?? consider DFS in sequence 5,6,7,8, apparently, the 8 has the smallest post value, but is not in sink.
- However, the vertex with biggest post time must be in source SCC. Assume  $u$  has the largest finish time, which must be a root of one DFS tree. Suppose  $u$  isn't in source SCC, i.e.  $\exists v$  s.t.  $(v, u)$  exists.  $v$  isn't in the tree of  $u$ , as  $(u, v)$  doesn't exist.  $v$  cannot start earlier than  $u$ ,  $v$  isn't in another DFS tree.
- Consider the meta-graph, where connected components form a big node, it must be DAG, else contradict with biggest SCC, therefore, there must be a sink. Also, a way to find whether  $v$  is reachable from  $u$  is to check the connectivity of bigger SCCs,  $U$  and  $V$ .

**Algorithm 6:** Strongly Connected Component

---

**Input:** DAG:G  
**Output:** num of SCC

```

1  Deduce  $G$ 's inverse  $G^R$  from  $G$ 
2  Run DFS on  $G^R$  to find source SSC, which is sink SSC of  $G$ , record it in the descending finish time as F.
3  DFS on  $G$  in the order of F.

```

---

**Algorithm 7:** alg:bfs

---

```

1 Queue Q;
2 Function bfs( $s, Q, u$ ):
3   for each  $v \in V$   $marked[v] \leftarrow false$ 
4    $Q.push(s)$   $marked[s] \leftarrow true$  while  $Q$  is not empty do
5      $u = Q.top(); Q.pop();$ 
6     foreach  $(u, v) \in E$  do
7       if  $marked[v] = false$  then
8          $marked[v] = True$ 
9          $Q.push(v)$ 
10      end
11    end
12  end

```

---

**2.3 BFS****2.4 Dijkstra**

Dijkstra's algorithm runs on positive-edge graph. It updates all vertice connected to the visited set and drag the closest vertex into the set. We conduct  $|V|$  insert and  $|E|$  update, each operation taking  $O(\log n)$ ,  $O((|E| + |V|) \log |V|)$ . If there exists  $x \notin SPT, v \in SPT$ , s.t.  $dist(s \rightarrow x \rightarrow v) < dist(v)$ ,  $dist(x) < dist(v)$ ,  $x$  should be in  $SPT$ , contradiction!

**Algorithm 8:** Di(j)kstra

---

**Input:**  $G=(V,E), s$   
**Output:**  $dist(u)$  is the shortest distance from  $s$  to  $u$

```

1 foreach  $u \in V$  do
2    $dist(u) = inf$ 
3    $pre(u) = Nan$  # initialize
4 end
5  $dist(s) = 0$ 
6  $H = makequeue(V)$ 
7 while  $H$  is not empty do
8    $u = H.top(); H.pop();$ 
9   foreach  $(u, v) \in E$  do
10    if  $dist(v) > dist(u) + l(u, v)$  then
11       $dist(v) = dist(u) + l(u, v)$  # update the shortest dist
12       $pre(v) = u$  # record previous node
13    end
14  end
15 end

```

---

**2.5 Bellman-Ford**

The key idea of Bellman-Ford is that it updates all the edges (kind of 'edgewise' operation) each time (different from Dijkstra's algorithm who updates nodes one step connected to SPT), which takes  $O(|V||E|)$ .

**Correctness of algorithm:**

**Algorithm 9:** Bellman-Ford

---

**Input:**  $G=(V,E),s$   
1  $\text{dist}[s]=0, \text{dist}[x]=\text{inf}$  for vertex other than  $s$   
2  $\text{pre}(v)=\text{Nan}$   
3 **while** *some dist[x] updates* **do**  
4     # update at most  $|V|$  rounds. **foreach**  $(u,v) \in E$  **do**  
5         **if**  $\text{dist}[v] > \text{dist}[u] + w(u,v)$  **then**  
6              $\text{dist}[v]=\text{dist}[u]+w(u,v)$   
7              $\text{pre}(v)=u$   
8         **end**  
9     **end**  
10 **end**

---

1. After  $k$  rounds,  $\text{dist}(v)$  is the shortest path of all  $k$ -edge-paths. ( $\text{dist}[u_k] \leq d(u_1, u_2, \dots, u_k)$ )  
For base step,  $\text{dist}[s]$  is the shortest dist of all 0-edge-paths.  
For induction step, suppose it is true for  $k-1$  rounds,  $\text{dist}[u_{k-1}] \leq d(u_1, \dots, u_{k-1})$ . By Bellman-ford update condition,  $\text{dist}[u_k] \leq d(u_1, \dots, u_{k-1}) + w(u_{k-1}, v)$ , the righthand side means all the other  $k$ -edge-paths.
2. For graphs without negative cycle, all the shortest paths will have at most  $|V| - 1$  edges.  
If there are more than  $|V|$  paths, a vertex must be visited twice, but by erasing the whole cycle results in a shorter path, contradiction!
3. Negative cycle exists iff some dist is updated in the last  $(|V|^{th})$  round.
4. If no vertice updates in  $V^{th}$  round, then no vertice will be updated then. But if a single vertice is not updated.
5. If a vertex is upgraded after  $V$  rounds, then its path must include a negative cycle. A negative cycle can be found by tracing the recorded shortest path until two repeated nodes occurs. Tricks include running till the  $2|V|^{th}$  round and see the vertice upgraded in  $|V|^{th}$  and  $2|V|^{th}$ .

### 3 Greedy Algorithm

#### 3.1 Prim

Adding the edge out of the previous Tree  $T_i$  with the minimum weight to form  $T_{i+1}$ .

**Correctness of algorithm:**

The key idea for Prim is to guarantee that the tree with  $n$  edges  $T_n$  is a subset of **global** MST  $T$ . In inductive step, if  $T_i$  is part of  $T$ , then we can construct  $T_{i+1}$ , s.t.  $T_{i+1} \in T$ . Consider the first edge  $e$  out of  $T_i$ , if  $e = (u,v) \notin T$ , then adding  $e$  to  $T$  constructs a cycle  $C$ . Since  $e$  rather than  $e' \in C, e' \notin T_i, e' \in T, w(e') \geq w(e)$ . Since  $T$  is the smallest spanning tree,  $T - w(e') + w(e) \geq T$ ,  $w(e) \geq w(e')$ , therefore,  $w(e) = w(e')$ . Therefore, by shifting the two edges guarantees  $T_{i+1}$  is a MST component of  $T$ .

**Time complexity:**  $O((|E| + |V|) \log(|V|))$ .

#### 3.2 Kruskal

$O(|E| \log(|E|))$  for sorting edges, and  $|E|$  iterations of finding the representative element. A faster data structure is by **unified set**, which is  $O(|E| \log(|V|))$

**Algorithm 10:** Kruskal's Algorithm

---

```

1 Sort the edge set E to ascending order.
2 X={}
3 For each  $u \in V$ , makeset( $u$ ). #  $|V|$  create group
4 For each  $(u, v) \in E$  in ascending order
5 if  $find(u) \neq find(v)$  then
6   | Add edge  $(u, v)$  to X
7   | union ( $u, v$ )
8 end
9 Function makeset( $x$ ):
10  |  $\pi(x) = x$ 
11  |  $rank(x) = 0$ 
12 Function find( $x$ ):
13  | while  $\pi(x) \neq x$  do
14  |   |  $\pi(x) = find(\pi(x))$ 
15  | end
16  | return  $x$  # path Compression
17 Function union( $x, y$ ):
18  |  $r_x = find(x)$  #  $r_x$  means root(representative) of  $x$ 
19  |  $r_y = find(y)$ 
20  | if  $r_x = r_y$  then
21  |   | return # already in the same group
22  | end
23  | if  $rank(r_x) > rank(r_y)$  then
24  |   |  $\pi(r_y) = r_x$  # merge the smaller tree to the bigger tree
25  | end
26  | if  $rank(r_x) = rank(r_y)$  then
27  |   |  $rank(r_y) = rank(r_y) + 1$ 
28  | end

```

---

**3.3 set coverage**

Denote  $S_l = \{A_1, \dots, A_l\}$  as the out put of greedy after  $l$  iterations,  $S^* = \{O_1, \dots, O_k\}$  be **any** collection of  $k$  subsets.

$$f(S_l) \geq (1 - (1 - 1/k)^l) f(S^*)$$

For base step,  $l = 1$ , by greedy nature,  $f(S_1 = A_1) \geq f(O_i)$  for all  $O_i$ . Thus  $f(S_1) \geq \frac{1}{k} \sum_{O_i \in S^*} f(O_i) = (1 - (1 - \frac{1}{k})^1) f(S^*)$  This implies when calculating the sum, union elements are calculated more than once. Also, the size of the first chosen set is larger than the average size of the optimal solution. Denote  $\Delta(O_i | S_t) = f(S_t \cup O_i) - f(S_t)$ .  $\Delta(A_{t+1} | S_t) \geq \frac{1}{k} \sum_{i=1}^k \Delta(O_i | S_t) \geq \frac{1}{k} \Delta(S^* | S_t)$ .

For inductive step, suppose  $f(S_t) \geq (1 - (1 - 1/k)^t) f(S^*)$

$$f(S_{t+1}) - f(S_t) \geq \frac{1}{k} (f(S^* \cup S_t) - f(S_t)) \geq \frac{1}{k} (f(S^*) - f(S_t)).$$

$$f(S_{t+1}) \geq \frac{1}{k} f(S^*) + (1 - \frac{1}{k}) f(S_t) \geq \frac{1}{k} f(S^*) + (1 - \frac{1}{k}) (1 - (1 - 1/k)^t) f(S^*) = ((1 - (1 - 1/k)^{t+1}) f(S^*)).$$

For max-k-coverage, we at most choose  $k$  sets.  $\lim_{k \rightarrow \infty} (1 - (1 - 1/k)^l) = 1 - 1/e$ .

For set cover problem, it is a  $\ln n$  approximation. Suppose  $|S^*| = k$  is optimal ( $f(S^*) = n$ ).  $f(S) \geq (1 - (1 - 1/k)^{k \cdot \ln n}) f(S^*) > (1 - 1/e^{\ln n}) f(S^*) = n - 1$  Therefore,  $f(S) = n$ .

### 3.4 Huffman Coding

The more frequent an encoding appears, the shorter the encoding is. Denote  $T$  as the Huffman Tree, and  $T'$  the tree that switched  $u, v$ , where  $\text{len}(u) < \text{len}(v)$ ,  $w(u) > w(v)$ .  $\text{avg\_len}(T) - \text{avg\_len}(T') = w(u) \cdot \text{len}(u) + w(v) \cdot \text{len}(v) - w(v) \cdot \text{len}(u) - w(u) \cdot \text{len}(v) = (w(u) - w(v))(\text{len}(u) - \text{len}(v)) < 0$ .

Next, we'll guarantee that every next step is optim, i.e.  $T_{i-1}$  is part of  $T$ . For base step,... For inductive step: If we merge  $A$  and  $B$  in  $T$ . If  $A$  is paired with  $C$  in  $T^*$ , then  $w(C) > w(A)$ ,  $w(B) \leq w(C)$ . If  $w(B) = w(C)$ , changing  $B$  and  $C$  preserves  $\text{avg\_len}$ . If  $w(B) < w(C)$ ,  $\text{len}(B) \geq \text{len}(C)$  by above proof. If  $\text{len}(B) = \text{len}(C)$ , swapping  $B$  and  $C$  also preserves  $\text{avg\_len}$ . If  $\text{len}(B) > \text{len}(C)$ ,  $D$  is not processed,  $w(D) > \max(w(A), w(B))$ , but  $\text{len}(D) = \text{len}(B) > \text{len}(C)$ , contradict with the fact that  $T^*$  is optimal (by above proof).

Another interpretation is by sorting inequality, namely, the sum of  $\sum \text{ordered\_sequence} \leq \sum \text{random\_sequence} \leq \sum \text{inversed\_sequence}$ .

**time complexity:** By using binary-heap, every time we conduct pop twice to obtain the top two min vertex and a push to add the new parent vertex in the tree, which takes  $O(n \log n)$ .

### 3.5 k-center

- **Algorithm:** Iteratively pick the center farthest to the existing centers. Pick the first by random. by Dijkstra for weighted graph and BFS for unweighted.

- The algorithm is **2-approximation**.

Denote  $OPT = \max \min d(o_1, v)$ .  $A = \{a_1, \dots, a_k\}$  for algorithm result,  $X_i = \{v_1, \dots, v_i\}$  as the set of vertex closest to  $o_i$ , optim solution  $O = \{o_1, \dots, o_k\}$

Case 1: Suppose  $A \cap X_i \neq \emptyset$  for all  $i$ . Then each  $X_i$  contains a center, as the biggest length between two vertex in  $X_i$  is smaller than  $2OPT$  by triangle inequality.

Case 2: Suppose  $\exists A \cap X_i = \emptyset$ . Suppose we choose  $a_j$  and  $a_r \in X_i$ . Let  $a_r$  be the second center chosen in  $X_i$ . By greedy choice, before  $a_r$  was chosen, the algorithm answer  $ALG = d(A, a_r) \leq d(a_j, a_r)$ . Additionally,  $d(a_j, a_r) \leq d(a_j, o_i) + d(a_r, o_i) \leq 2OPT$ .

### 3.6 max-cut

- Start with any partition  $\{A, B\}$ . If moving a vertex  $u$  from  $A$  to  $B$  or from  $B$  to  $A$  increases  $c(A, B)$ , move it. Terminate until no such movement is possible
- **Time Complexity** checking whether to update takes  $O(|E|)$ , every update you earns at least an edge, so it takes  $O(|E|)$  rounds. The total algorithm is  $O(|E|^2)$ , polynomial!
- **Approximation** When the algorithm terminates,  $\forall u$ , at least  $0.5 \deg(u)$  edges are in the cut, which leads to a 0.5-approximation.

$$c(A, B) \geq \frac{1}{2} \sum_{u \in V} \frac{1}{2} \deg(u) = \frac{1}{2} |E|$$
